security is a rapidly growing area of computer science with direct and increasing relevance to real life applications such as internet transactions e commerce information protection network and systems security etc foundations for the analysis and design of security features of such applications are badly needed in order to validate and prove their correctness this book presents thoroughly revised versions of six tutorial lectures given by leading researchers during two international schools on foundations of security analysis and design fosad 2001 2002 held in bertinoro italy in september 2001 and september 2002 the lectures are devoted to formal approaches to approximating noninterference properties the key establishment problem name passing calculi and cryptoprimitives classification of security properties network security cryptographic algorithms for multimedia traffic security for mobility

this book is based on material presented at the international summer school on applied semantics that took place in caminha portugal in september 2000 we aim to present some recent developments in programming language research both in semantic theory and in implementation in a series of graduate level lectures the school was sponsored by the esprit working group 26142 on applied semantics appsem whichoperatedbetweenapril1998andmarch2002 the purpose of this working group was to bring together leading reseachers both in semantic theory and in implementation with the speci c aim of improving the communication between theoreticians and practitioners theactivitiesofappsemwerestructuredintonineinterdisciplinarythemes a semantics for object oriented programming b program structuring c integration of functional languages and proof assistants d veri cation methods e automatic program transformation f games sequentiality and abstract machines g types and type inference in programming h semantics based optimization i domain theory and real

an introduction to fundamental theories of concurrent computation and associated programming languages for developing distributed and mobile computing systems starting from the premise that understanding the foundations of concurrent programming is key to developing distributed computing systems this book first presents the fundamental theories of concurrent computing and then introduces the programming languages that help develop distributed computing systems at a high level of abstraction the major theories of concurrent computation including the π calculus the actor model the join calculus and mobile ambients are explained with a focus on how they help design and reason about distributed and mobile computing systems the book then presents programming languages that follow the theoretical models already described including pict salsa and jocaml the parallel structure of the chapters in both part one theory and part two practice enable the reader not only to compare the different theories but also to see clearly how a programming language supports a theoretical model the book is unique in bridging the gap between the theory and the practice of programming distributed computing systems it can be used as a textbook for graduate and advanced undergraduate students in computer science or as a reference for researchers in the area of programming technology for distributed computing by presenting theory first the book allows readers to focus on the essential components of concurrency distribution and mobility without getting bogged down in syntactic details of specific programming languages once the theory is understood the practical part of implementing a system in an actual programming language becomes much easier

this book offers a concise treatment of multiplicative ideal theory in the language of multiplicative monoids it presents a systematic development of the theory of weak ideal systems and weak module systems on arbitrary commutative monoids examples of monoids that are investigated include but are not limited to mori monoids laskerian monoids prüfer monoids and krull monoids an in depth study of various constructions from ring theory is also provided with an emphasis on polynomial rings kronecker function rings and nagata rings the target audience is graduate students and researchers in ring and

this work starts with the study of those limit theorems in probability theory for which classical methods do not work in many cases some form of linearization can help to solve the problem because the linearized version is simpler but in order to apply such a method we have to show that the linearization causes a negligible error the estimation of this error leads to some important large deviation type problems and the main subject of this work is their investigation we provide sharp estimates of the tail distribution of multiple integrals with respect to a normalized empirical measure and so called degenerate u statistics and also of the supremum of appropriate classes of such quantities the proofs apply a number of useful techniques of modern probability that enable us to investigate the non linear functionals of independent random variables this lecture note yields insights into these methods and may also be useful for those who only want some new tools to help them prove limit theorems when standard methods are not a viable option
